## Question 1

Your goal is to predict abalone age, which is calculated as the number of rings plus 1.5. Notice there currently is no age variable in the data set. Add age to the data set.

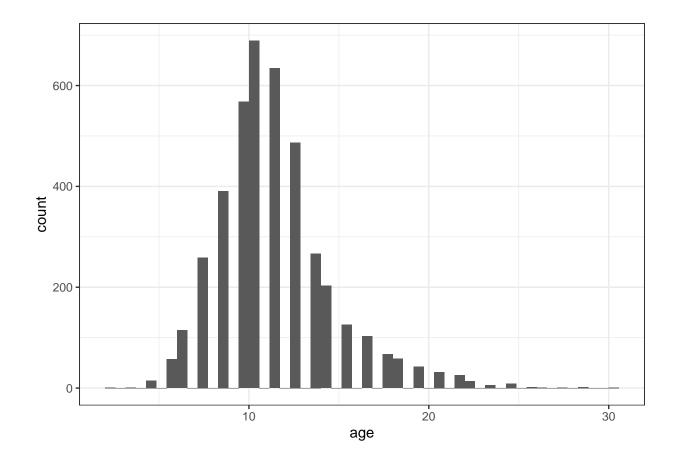

```
abalone <- read.csv("abalone.csv")

new_abalone <- abalone %>%
  mutate(age = rings + 1.5)
```

Assess and describe the distribution of age.

As we access the distribution of the new variable age, we can see it looks relatively normal, but is skewed a bit to the right, centering around 10.

```
new_abalone %>%
ggplot(aes(x = age)) +
geom_histogram(bins = 50) +
theme_bw()
```

Split the abalone data into a training set and a testing set. Use stratified sampling. You should decide on appropriate percentages for splitting the data.

Remember that you'll need to set a seed at the beginning of the document to reproduce your results.

## type longest\_shell diameter height whole\_weight shucked\_weight

##	5	I	0.330	0.255	0.080	)	0.2050	0.0895
##	6	I	0.425	0.300	0.095	5	0.3515	0.1410
##	17	I	0.355	0.280	0.085	5	0.2905	0.0950
##	19	M	0.365	0.295	0.080	)	0.2555	0.0970
##	36	M	0.465	0.355	0.105	5	0.4795	0.2270
##	43	I	0.240	0.175	0.045	5	0.0700	0.0315
##		viscera_weigh	nt shell	_weight	rings	age		
##	5	0.039	95	0.055	7	8.5		
##	6	0.077	75	0.120	8	9.5		
##	17	0.039	95	0.115	7	8.5		
##	19	0.043	30	0.100	7	8.5		
##	36	0.124	10	0.125	8	9.5		
##	43	0.023	35	0.020	5	6.5		

Using the **training** data, create a recipe predicting the outcome variable, **age**, with all other predictor variables. Note that you should not include **rings** to predict **age**. Explain why you shouldn't use **rings** to predict **age**.

I should not use rings to predict age, because we have used rings to calculate age in step 1, and we wont be able to see how other predictors can predict by having rings as one of the predictors, since we already have age = rings + 1.5 function.

Steps for your recipe:

1. dummy code any categorical predictors

```
new_abalonegender_m < -ifelse(new_abalonetype == "M", 1, 0)

new_abalonegender_f < -ifelse(new_abalonetype == "F", 1, 0)

new_abalonegender_i < -ifelse(new_abalonetype == "I", 1, 0)

this don't seem to work with the latter steps
```

```
##
                                         diameter
             type longest_shell
                                                           height
                                                                     whole_weight
                        "numeric"
                                        "numeric"
                                                        "numeric"
##
      "character"
                                                                        "numeric"
## shucked_weight viscera_weight
                                     shell_weight
                                                            rings
                                                                              age
##
        "numeric"
                        "numeric"
                                        "numeric"
                                                        "integer"
                                                                        "numeric"
```

- 2. create interactions between
  - type and shucked\_weight,
  - longest\_shell and diameter,
  - shucked\_weight and shell\_weight
- 3. center all predictors, and
- 4. scale all predictors.

You'll need to investigate the tidymodels documentation to find the appropriate step functions to use. Creating recipe

```
new_abalone %>%
 head()
     type longest_shell diameter height whole_weight shucked_weight viscera_weight

##	-0.44729	-0.06153

Now you want to assess your model's performance. To do this, use the yardstick package:

- 1. Create a metric set that includes  $R^2$ , RMSE (root mean squared error), and MAE (mean absolute error).
- 2. Use predict() and bind\_cols() to create a tibble of your model's predicted values from the training data along with the actual observed ages (these are needed to assess your model's performance).
- 3. Finally, apply your metric set to the tibble, report the results, and interpret the  $\mathbb{R}^2$  value.

From what we got for  $R^2$  which is roughly 0.55, it is not significant enough to show a strong correlation, it can only be considered relatively strong, but it is not significant enough to compare with our initial function which is age = rings + 1.5. Though the question didn't require us to plot a graph, but the scatter plot should be a clear visual representation that our model didn't do well.

```
abalone_train %>% head()
```

```
